

APPENDIX A – DEL 1 af 2

A1 Model area for the two study: Ringkøbing fjord catchment and Mid-Zealand catchment

Figur A1-1 til A1-3 viser de to forskellige oplande i NIFA-projektet: (1) Oplandet til Ringkøbing fjord og (2) Oplandet til Suså-Tryggevælde å-Langvand å i Midtsjælland. De to oplande er velegnede til opgaven, da de opfylder behov for problemstillinger med akvifer bæredygtighed (saltvandsind- og optrængning) samt påvirkning af recipientmæssig bæredygtighed (environmental/ecological flow) (Navarro and Schmidt, 2012; Arthington & Tharme, 2003; Henriksen and Refsgaard, 2013).

I figurerne ses afgrænsningen af det modellerede modelområdet for de to oplande. På kortene er desuden vist topografi, vandløbssetup (incl. tilføjede små vandløb vist med lyseblåt), placering af vandføringsmålestationer(Q-stationer) samt performance (NSE) for modelkørsler fra 1989-2018(de historiske modelkørsler).

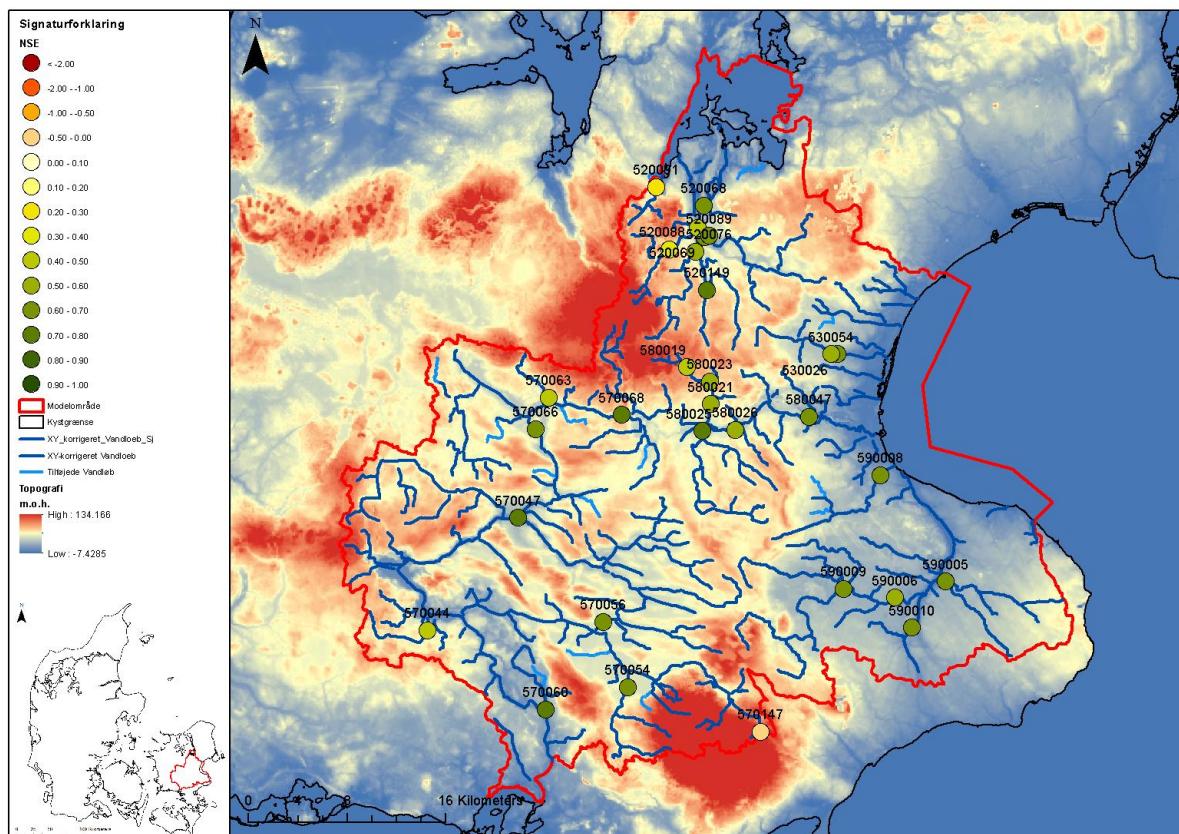

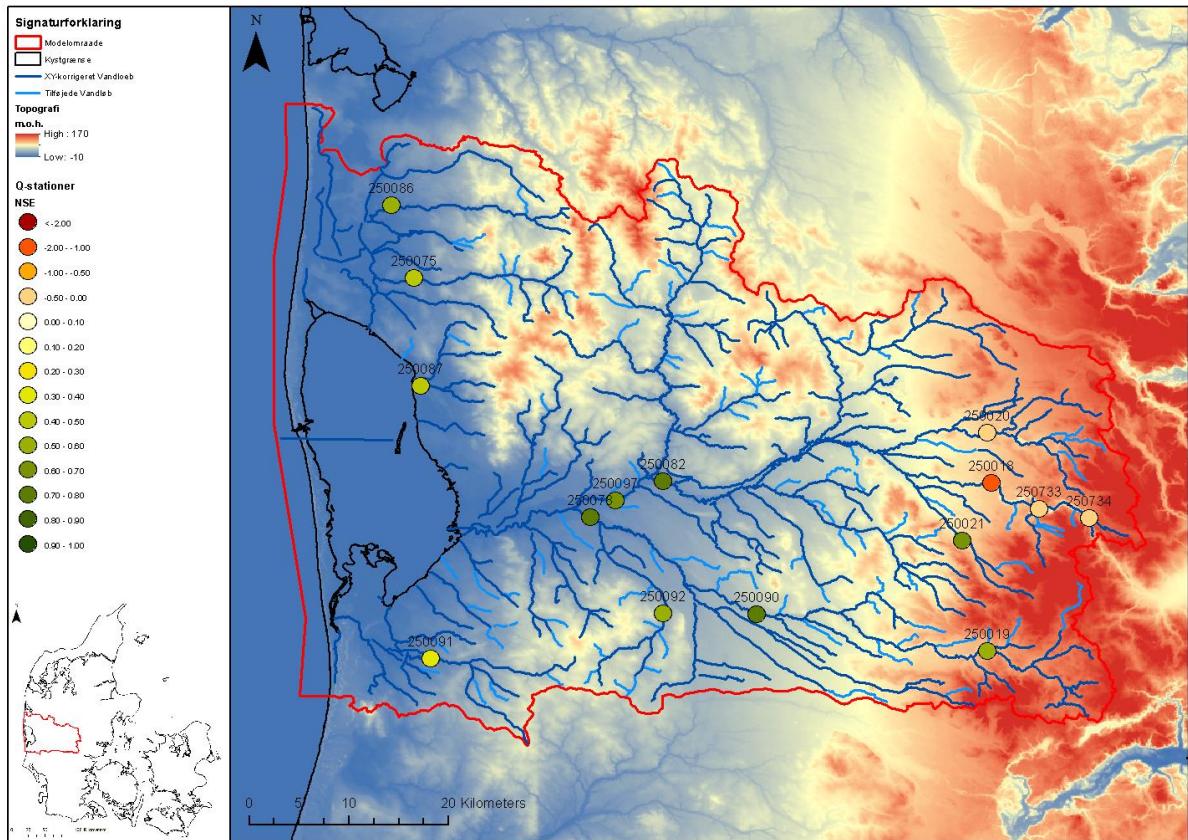

Figure A1-1: Location and the performance (NSE) for the discharge station in the Ringkøbing catchment (upper figure) and in Mid-Zealand catchment (lower figure).

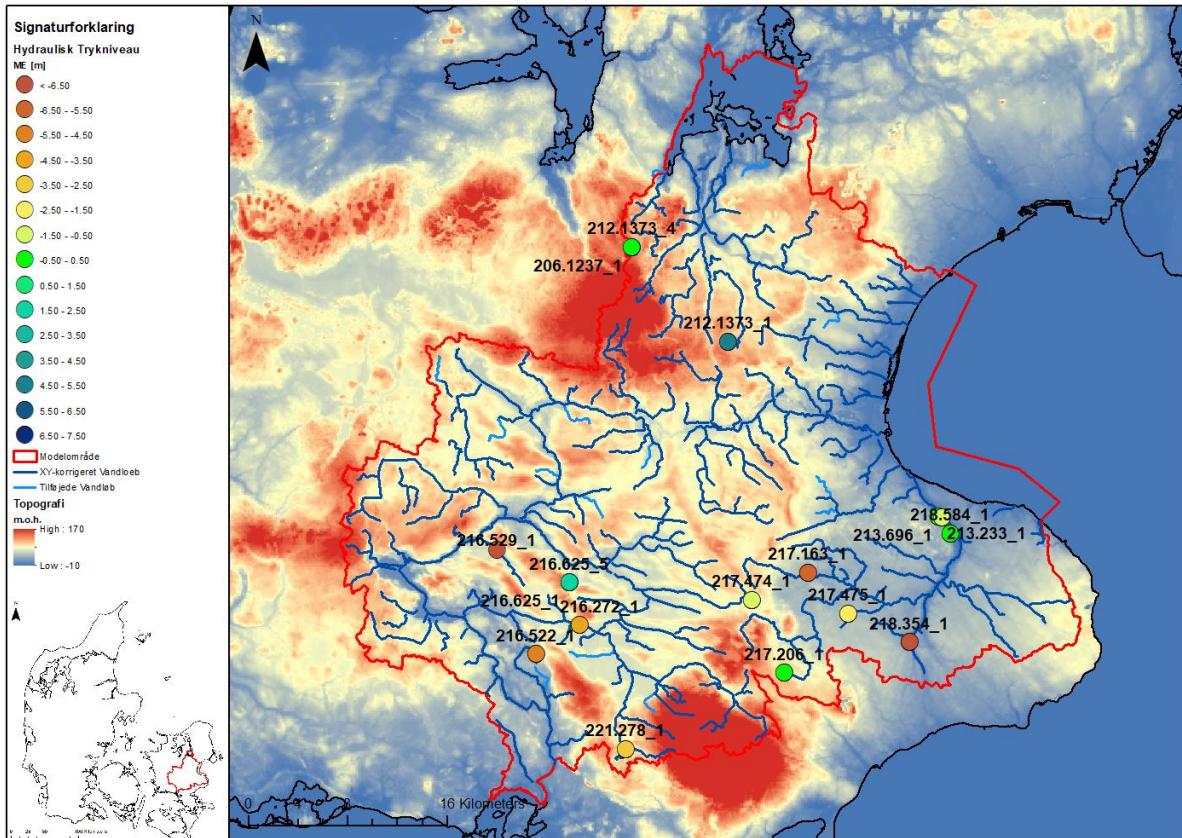

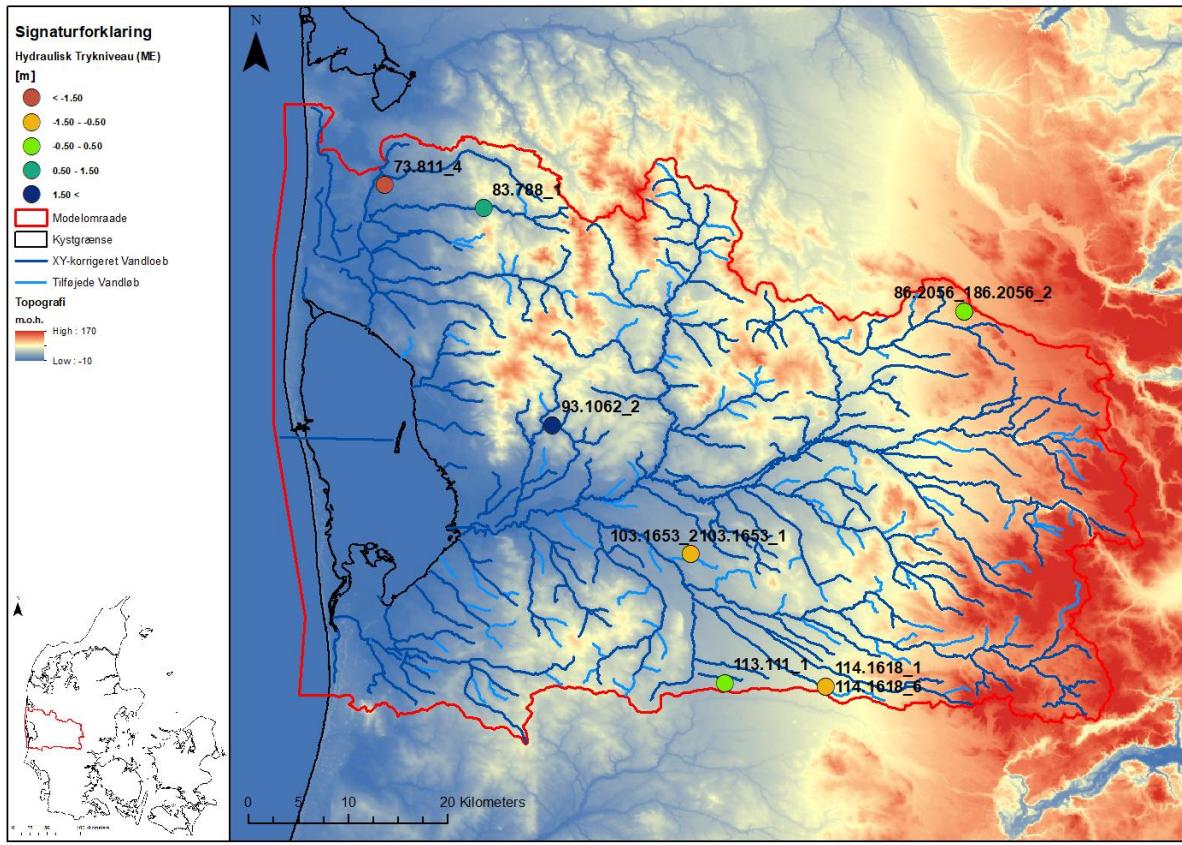

Figure A1-2: Figure shows the location and the performance (ME) for the wells in the Ringkøbing catchment(upper figure) and in Mid-Zealand catchment(lower figure).

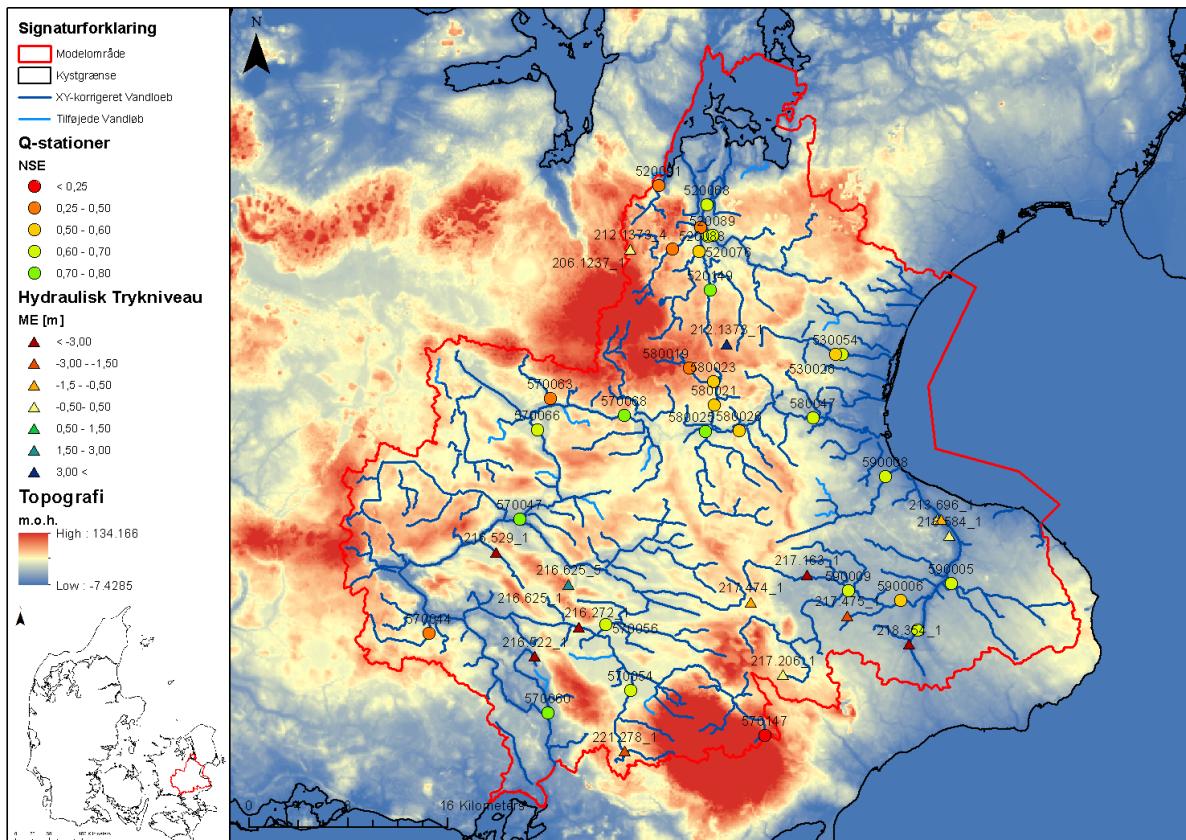

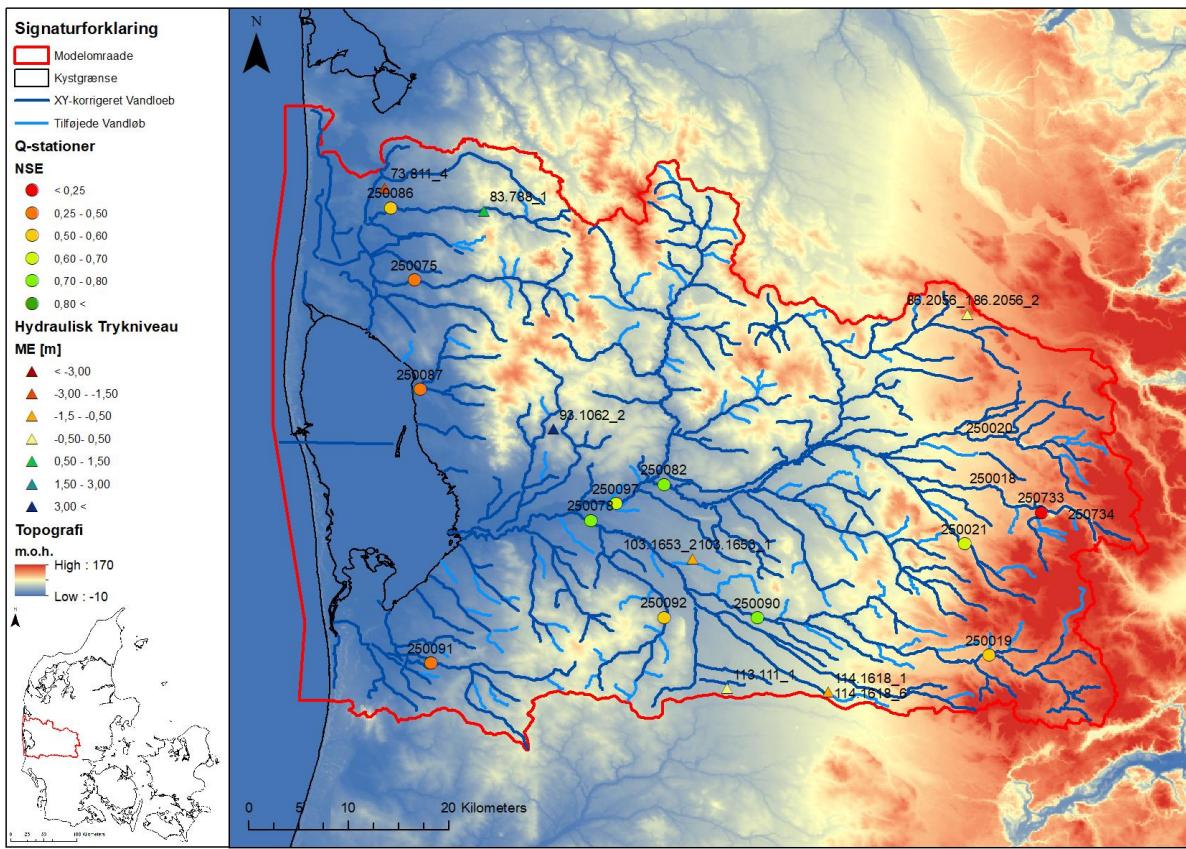

Figure A1-3: The two selected case studies with location of river discharge stations.

A2 Model performances – selected timeseries in supplementary material

For modellerne for oplandene til Ringkøbing fjord og Midtsjælland er modellernes prædiktionsevne og fejl vurderet (performance tests) for de opstillede 200 m modeller ved sammenligning med DK-model2019 samt på basis af observerede klimadata. Begge modeller er kørt for 1989-2018 hvorefter der er udtrukket middelfejl (ME), root mean square error (RMSE, som er et på bud på usikkerheden på den gennemsnitlige prædiktionsfejl) og NashSutcliffe efficiency coefficient (NSE-R2, som mål for modellernes prædiktionsevne).

Resultatet af performance testen har vist at der er opnået samme eller forbedret performance i forhold til moniteringsfiltre (nationale pejletidsserier) i de to oplande. Afstrømninger i 7 udvalgte vandløb i både Ringkøbing fjord og Midtsjælland opland, er modelleret på et performanceniveau der svarer til DK-model2019.

Model performance for Ringkøbing catchment

Table A2-1: Performance kriteria for Ringkøbing catchment model runned with 500x500m grid and 200x200m grid, respectively .

Modeller (Head)	ME [m]	MAE [m]	RMSE [m]
Ringkøbing catchment - 500m	-0.65	1.24	1.34
Ringkøbing catment - 200m	-0.02	1.03	1.10

Table A2-2: Model performance fpr selected discharge-stations for Ringkøbing catchment model runned with 500x500m grid and 200x200m grid, respectively

Udvalgte Q-stationer	Ringkøbing - 500m [NSE]	Ringkøbing - 200m [NSE]
Q250021 (BRANDE_AA, 4300.000)	0.79	0.67

Q590009 (SAVL4_DK1, 7185.000)	0.72	0.63
Mean of 7 stations	0.59	0.64

A3: Water balances (Ringkøbing fjord opland and Midtsjælland model area):

Historical observed climate 1989-2018

Nedenstående figur A3 viser en grafisk afbilledning af den totale vandbalance for den historiske kørsel (1989-2018) for oplandet til Ringkøbing fjord og oplandet til Suså-Tryggevælde å-Køge å-Langvand å i Midtsjælland. Den historiske kørsel er modelleret med observerede klimadata. Den totale vandbalance er udregnet i mm/år, og beregnet som et gennemsnit af den 30-årig historiske periode. Den totale vandbalance er beregnet indenfor landområderne i modelområderne for de to oplande, for dermed ikke at medregne hav-områder og fjorde i den totale vandbalance.

Oplandet til Ringkøbing Fjord er karakteriseret ved en stor udstrømning af grundvand til vandløbssystemet, hvorimod oplandet på Midtsjælland er karakteriseret ved begrænset grundvandsudveksling, mens drænvandskomponenten har relativt stor betydning. Desuden er der store klimatiske forskelle på de to oplande, hvor nedbøren i Vestjylland er signifikant større end nedbøren på Midtsjælland. Samtidig er grundvandsindvinding til husholdning betydeligt lavere i Vestjylland, som dog i tørre år kan have en betydelig indvinding til markvanding (se Figur A3).

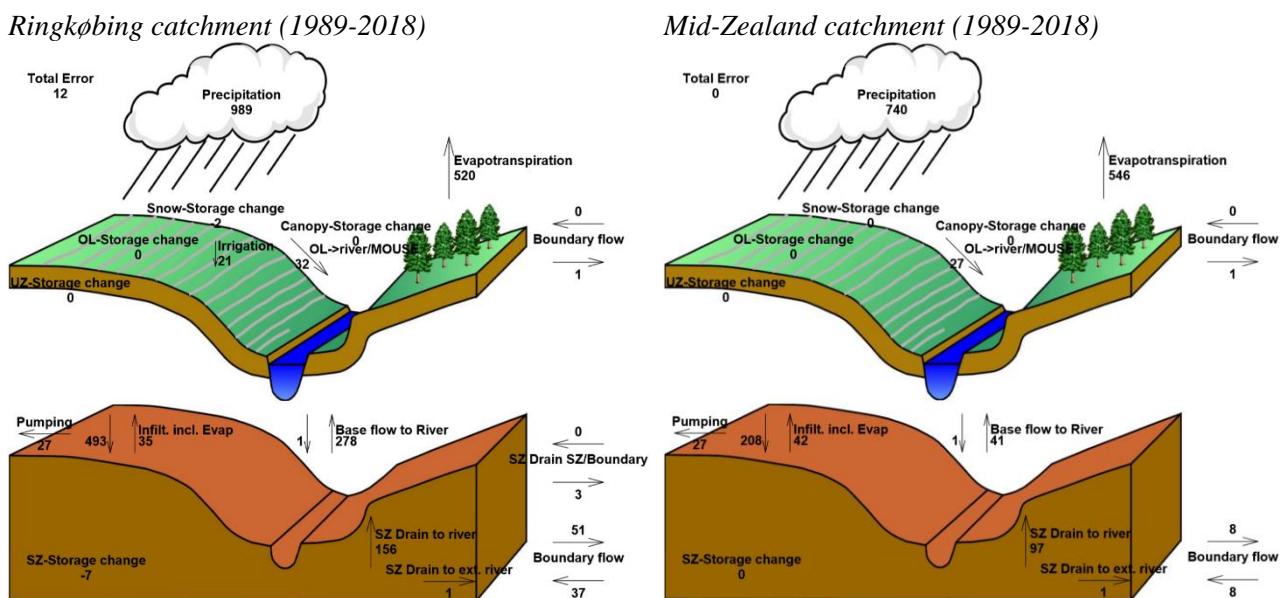

Figure A2: Water balance graphic, in mm per year simulated in 1990-2018, for Ringkøbing catchment and Mid-Zealand, respectively.

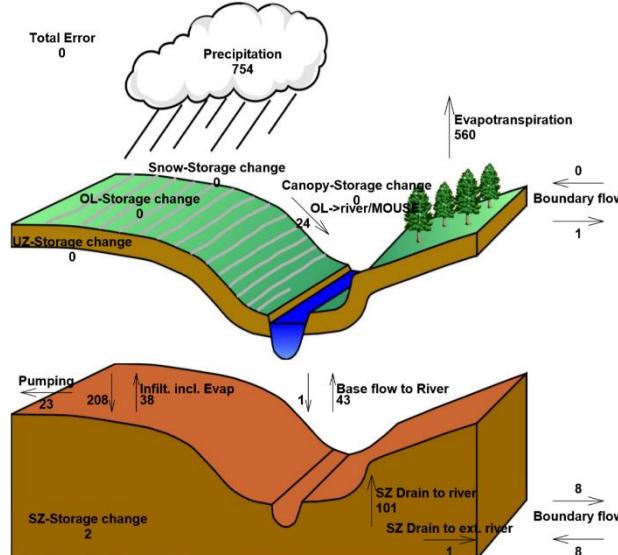

Reference and climate models

Nedenstående figurer viser grafiske afbilledninger af den totale vandbalance for reference kørsel (1981-2010) og for klimakørslen for hhv. oplandet til Ringkøbing fjord og oplandet i Midtsjælland. Der er anvendt i alt fire forskellige scenarier i klimafremskrivningen: RCP8.5 wet climate model (IPSL-RCA), RCP8.5 median climate model (KNMI), RCP8.5 dry climate model (HIRHAM), samt RCP4.5 median climate model (HIRHAM). Både reference og klimakørslen er kørt med fire forskellige scenarier. Klimakørslerne med klimascenarierne RCP8.5 er kørt for perioden 2071-2100 og RCP4.5 er kørt for 2041-2070.

RCP4.5 (HIRHAM)

1981-2010

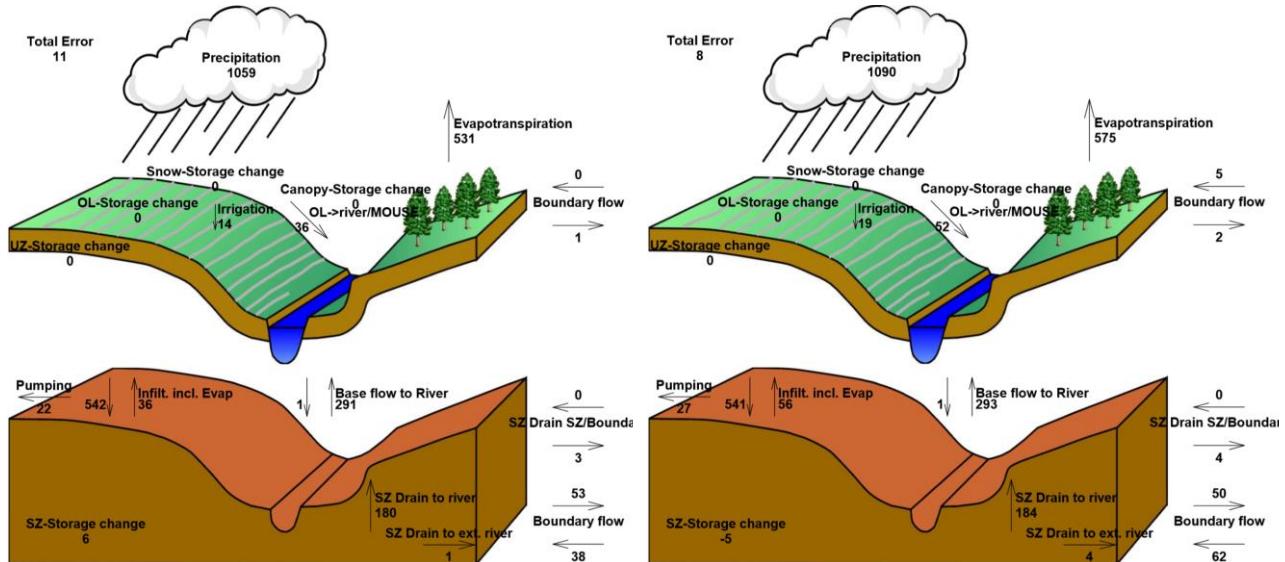

Figure A3-7: Water balance graphic for climate model the RCP4.5 (HIRHAM), in mm per year, simulated for Ringkøbing catchment for the periods 1981-2010(left) and 2041-2070 (right) .

Vandbalance klimafaktor

I nedenstående tabel ses en oversigt over klimaforandringernes indflydelse på den totale vandbalance for de fire forskellige klimascenarier målt vha. klimafaktor($\text{climate factor}_{\text{precip}} = \text{precip future climate} / \text{precip present climate etc.}$) for oplandet til Ringkøbing Fjord og oplandet i Midtsjælland. Desuden ses resultaterne for den historiske periode baseret på de observede klimainput(mm/år).

Table A3-1: Overall results of climate change impacts on water balances for the two catchments by calculated climate factor ($\text{climate factor}_{\text{precip}} = \text{precip future climate} / \text{precip present climate etc.}$). In italic is shown the results for the historical period based on observed climate inputs (mm/year).

The grey line represents the annual minimum flow levels in the historical model run in the period 1989-2018, whereas the grey points represent the observed minimum flow levels in the same period (these observations are sorted by quantity distributed over a year). The blue line represent the annual minimum flow levels for the four climate models in the period 1981-2010, whereas the orange line represent the annual minimum flow levels for the four climate models in the period 2071-2100(RCP 8.5)/2041-2070(RCP 4.5).
